

## 2.5MHz, Synchronous Boost Regulator with Bypass Mode

### General Description

The RT4803 allows systems to take advantage of new battery chemistries that can supply significant energy when the battery voltage is lower than the required voltage for system power ICs. By combining built-in power transistors, synchronous rectification, and low supply current; this IC provides a compact solution for systems using advanced Li-Ion battery chemistries.

The RT4803 is a boost regulator designed to provide a minimum output voltage from a single-cell Li-Ion battery, even when the battery voltage is below system minimum. In boost mode, output voltage regulation is guaranteed to a maximum load current of 2A. Quiescent current in Shutdown Mode is less than 1 $\mu$ A, which maximizes battery life. The regulator transitions smoothly between Bypass and normal Boost Mode. The device can be forced into Bypass Mode to reduce quiescent current.

The RT4803 is available in the WL-CSP-16B 1.67x1.67 (BSC) package.

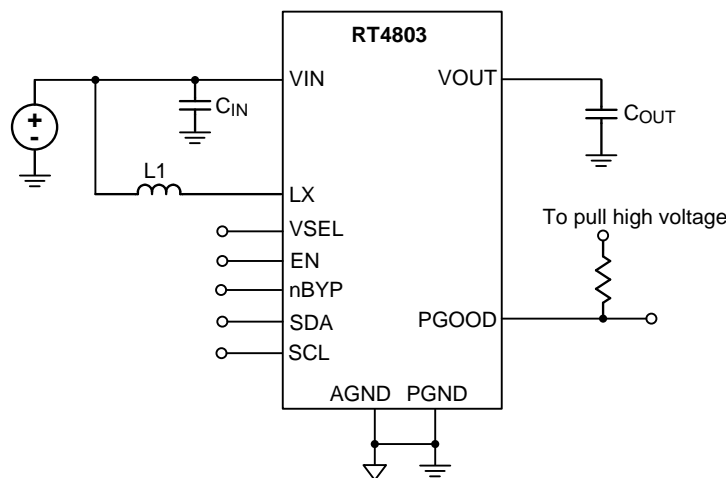

### Features

- **4 Few External Components : 0.47 $\mu$ H Inductor and 0603 Case Size Input and Output Capacitors**
- **Input Voltage Range : 1.8V to 5V**
- **Output Range from 2.85V to 4.4V**
  - ▶ **VSEL = L 3.3V**
  - ▶ **VSEL = H 3.55V**
- **Maximum Continuous Load Current : 2A at  $V_{IN} > 2.65V$  Boosting  $V_{OUT}$  to 3.35V**
- **Up to 96% Efficient**
- **True Bypass Operation when  $V_{IN} > \text{Target } V_{OUT}$**
- **Internal Synchronous Rectifier**
- **Soft-Start with True Load Disconnect**
- **Forced Bypass Mode**
- **$V_{SEL}$  Control to Optimize Target  $V_{OUT}$**
- **Short-Circuit Protection**
- **I<sup>2</sup>C Controlled Interface**
- **Ultra low Operating Quiescent Current**
- **Small WL-CSP 16B Package**
- **Discharge Function**

### Applications

- Single-Cell Li-Ion, LiFePO4 Smart-Phones or Tablet
- 2.5G/3G/4G Mini-Module Data Cards

### Simplified Application Circuit

## Ordering Information

RT4803 □  
 Package Type  
 WSC : WL-CSP-16B 1.67x1.67 (BSC)

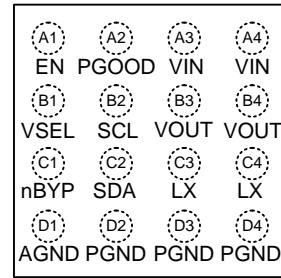

Note :

Richtek products are :

- ▶ RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- ▶ Suitable for use in SnPb or Pb-free soldering processes.

## Pin Configuration

(TOP VIEW)

WL-CSP-16B 1.67x1.67 (BSC)

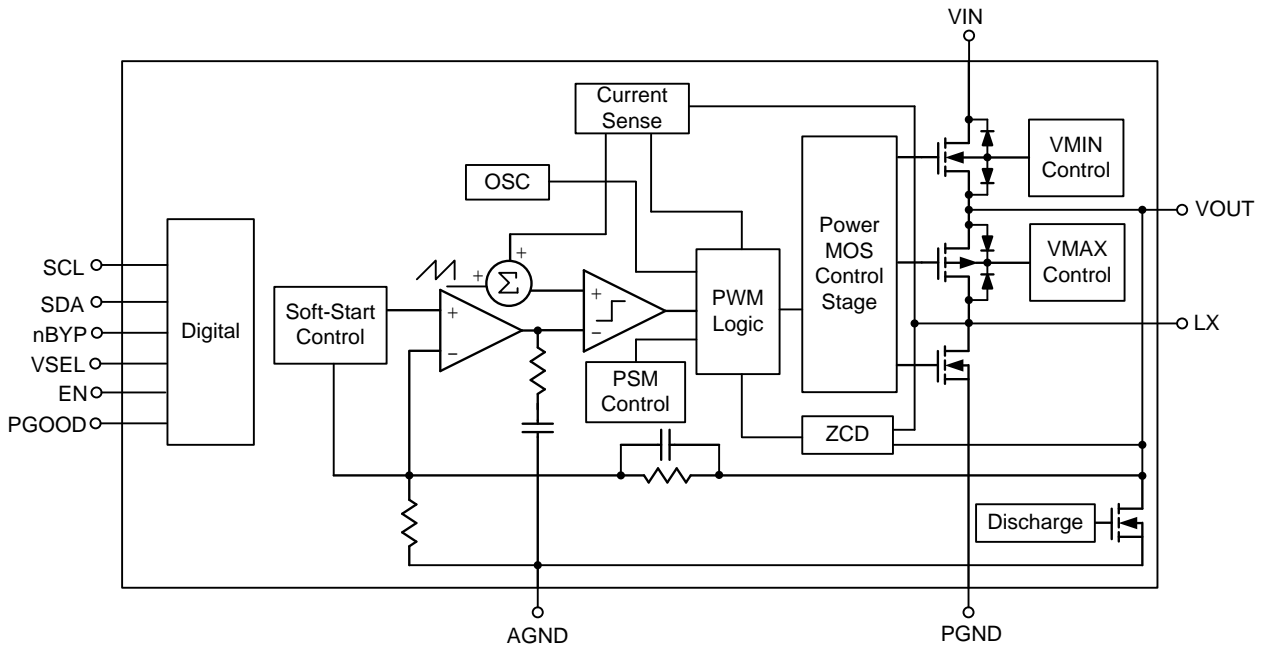

## Marking Information

## Functional Pin Description

Pin No.	Pin Name	Pin Function
A1	EN	Enable. When this pin is HIGH, the circuit is enabled.
A2	PGOOD	Power good. It is an open-drain output. PGOOD pin pulls low automatically if the overload or OTP event occurs.
A3, A4	VIN	Input voltage. Connect to Li-Ion battery input power source.
B1	VSEL	Output voltage select. When boost is running, this pin can be used to select output voltage
B2	SCL	Serial interface clock. (Pull down if I <sup>2</sup> C is non-used).
B3, B4	VOUT	Output voltage. Place C <sub>OUT</sub> as close as possible to the device.
C1	nBYP	Bypass. This pin can be used to activate Forced Bypass Mode. When this pin is LOW, the bypass switches are turned on and the IC is otherwise inactive.
C2	SDA	Serial interface data line. (Pull down if I <sup>2</sup> C is non-used).
C3, C4	LX	Switching node. Connect to inductor.
D1	AGND	Analog ground. This is the signal ground reference for the IC. All voltage levels are measured with respect to this pin.
D2, D3, D4	PGND	Power ground. This is the power return for the IC. The C <sub>OUT</sub> bypass capacitor should be returned with the shortest path possible to these pins.

**Functional Block Diagram**

### Operation

The RT4803 combined built-in power transistors, synchronous rectification, and low supply current, it provides a compact solution for system using advanced Li-Ion battery chemistries.

In boost mode, output voltage regulation is guaranteed to a maximum load current of 2A. Quiescent current in Shutdown mode is less than 1 $\mu$ A, which maximizes battery life.

Mode	Depiction	Condition
LIN	LIN 1	Linear startup 1 $V_{IN} > V_{OUT}$
	LIN 2	Linear startup 2 $V_{IN} > V_{OUT}$
Soft-Start	Boost soft-start	$V_{OUT} < V_{OUT(MIN)}$
Boost	Boost mode	$V_{OUT} = V_{OUT(MIN)}$
Bypass	Bypass mode	$V_{IN} > V_{OUT(MIN)}$

#### LIN State

When  $V_{IN}$  is rising, it enters the LIN State. There are two parts for the LIN state. It provides maximum current for 1A to charge the  $C_{OUT}$  in LIN1, and the other one is for 2A in LIN2. By the way, the EN is pulled high and  $V_{IN} > UVLO$ .

As the figure shown, if the timeout is over the specification, it will enter the Fault mode.

Figure 1. RT4803 State Chart

#### Startup and Shutdown State

When  $V_{IN}$  is rising and through the LIN state, it will enter the Startup state. If EN is pulled low, any function is turned-off in shutdown mode.

#### Soft-Start State

It starts to switch in Soft-start state. After the LIN state, output voltage is rising with the internal reference voltage.

There is a point, it will go to fault condition, if the large output capacitor is used and the timeout is over 2ms after the soft-start state.

#### Fault State

As the Figure 1 shown, it will enter to the Fault state as below,

- ▶ The timeout of LIN2 is over the 1024 $\mu$ s.
- ▶ It is over the 2ms when the state changed from Soft-start state to Boost mode.

It will be the high impedance between the input and output when the fault is triggered. A restart will be start after 1ms.

#### Boost Mode

There are two normal operation modes, one is the Boost mode, and the other one is Bypass mode. In the Boost mode, it provides the power to load by internal synchronous switches after the soft-start state.

#### Bypass Mode

In Bypass mode, the differential voltage between  $V_{IN}$  and  $V_{OUT}$  is 250mV. Output voltage will increase when the input voltage is rising after the soft-start state.

#### Bypass Mode Operation

In automatic mode, it transits from Boost mode to Bypass mode. As the Figure 2 shown, there are three MOSFET (Q1 to Q3). The Q1 & Q2 is for Boost mode, it is used by Q3 for Bypass mode.  $V_{OUT}$  will be followed the  $V_{IN}$  when  $V_{IN}$  is higher than the target output voltage. As the Figure 3 shown, it is transited by bypass MOSFET (Q3).  $V_{OUT}$  followed the  $V_{IN}$ .

Figure 2. Boost Converter With Bypass Mode

Figure 3. RT4803 mode changed

**Force Pass-Through Mode**

When EN pulled high and nBYP pulled low. The device is active in the Force pass-through mode. It supplies current is approximately 15μA typ. From the battery, the device is short circuit protected by a current limit of 4000mA.

**VSEL**

It is concerned the minimum output voltage at the heavy load condition. There are two output voltage levels (3.3V & 3.55V) in Boost mode and Bypass mode. It can be selected by VSET, so it must not be floating.

**PGOOD (Power Good)**

Power good is an open-drain input. If it is 0, it stands for a fault occurred. The power good provides the information to show the state of the system,

- PGOOD pin shows high when the sequence of soft-start is completed.
- Any fault causes PGOOD to be pulled low.
- PGOOD low when PMIS current limit has triggered for OR the die temperature exceeds 120°C. PGOOD is re-asserted when the device cools below 100°C.

**OCP**

The converter senses the current signal when the high-side P-MOSFET turns on. As a result, the OCP is cycle-by-cycle current limitation. If the OCP occurs, the converter holds off the next on-pulse until inductor current drops below the OCP limit.

**OTP**

The converter has an over-temperature protection. When the junction temperature is higher than the thermal shutdown rising threshold, the system will be latched and the output voltage will no longer be regulated until the junction temperature drops under the falling threshold.

**EN & nBYP**

It is used to select mode. As the table 1 shown, there are four device states.

If the EN pull low, and nBYP pull high/low, the RT4803 is forced in shut-down mode and the quiescent is less than 1μA. It works in force pass-through mode, if the EN set high and nBYP set low. When EN and nBYP both pull high, the RT4803 is normal operation and enters automatic mode. There should be a delay time (> 60μS) from EN pull high to nBYP pull high to guarantee normal automatic mode operation.

**Discharge**

The RT4803 features the discharge function to release the output power when the EN pin goes low condition.

Table 1

EN input	nBYP Input	Device State
0	0/1	The device is shut down and the shut down current is down to 1 $\mu$ A.
1	0	The device is active in forced pass-through mode. The device supply current is approximately 15 $\mu$ A typ. From the battery. The device is short circuit protected by a current limit of ca. 400mA.
1	1	The device is active in auto mode (dc/dc boost, pass-through mode) The device supply current is approximately 65 $\mu$ A typ. from the battery

**Absolute Maximum Ratings** (Note 1)

- VIN, VOUT to AGND ----- -0.2V to 6V
- EN, VSEL, PGOOD, nBYP to AGND ----- -0.2V to 6V
- LX ----- (PGND – 0.2V) to 6V
- Power Dissipation, P<sub>D</sub> @ T<sub>A</sub> = 25°C  
 WL-CSP-16B 1.67x1.67 (BSC) ----- 2.09W
- Package Thermal Resistance (Note 2)  
 WL-CSP-16B 1.67x1.67 (BSC), θ<sub>JA</sub> ----- 47.7°C/W
- Lead Temperature (Soldering, 10 sec.)----- 260°C
- Junction Temperature----- 150°C
- Storage Temperature Range----- -65°C to 150°C
- ESD Susceptibility (Note 3)  
 HBM (Human Body Model) ----- 2kV  
 MM (Machine Model)----- 200V  
 CDM (Charge Device Model)----- 1kV

**Recommended Operating Conditions** (Note 4)

- Input Voltage Range ----- 1.8V to 5V
- Output Voltage Range ----- 2.85V to 4.4V
- Ambient Temperature Range----- -40°C to 85°C
- Junction Temperature Range ----- -40°C to 125°C

**Electrical Characteristics**

(V<sub>IN</sub> = 3V, V<sub>OUT</sub> = 3.55V, T<sub>A</sub> = 25°C, unless otherwise specified)

Parameter	Symbol	Test Conditions	Min	Typ	Max	Unit

Over Temperature Protection Hysteresis	T <sub>OTP_HYS</sub>		--	20	--	°C
FAULT Restart Time	T <sub>RST</sub>		--	1	--	ms

**Note 1.** Stresses beyond those listed “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

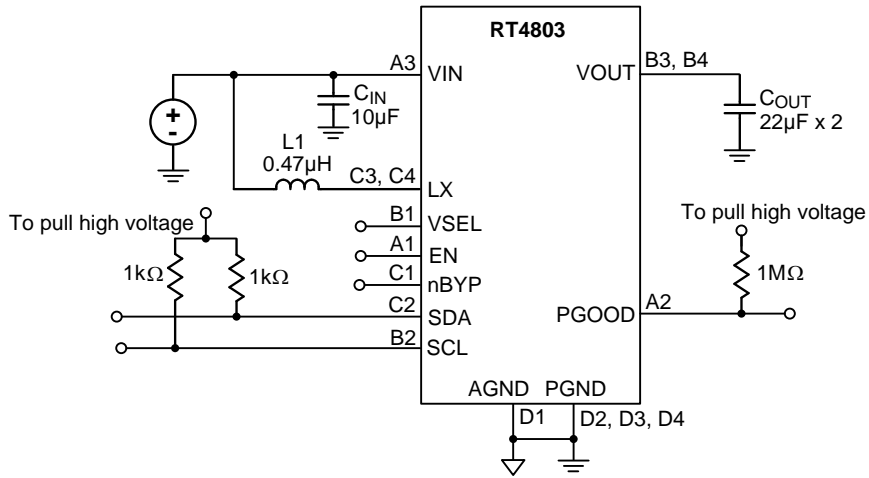

**Note 2.**  $\theta_{JA}$  is measured at T<sub>A</sub> = 25°C on a high effective thermal conductivity four-layer test board per JEDEC 51-7.

**Note 3.** Devices are ESD sensitive. Handling precaution recommended.

**Note 4.** The device is not guaranteed to function outside its operating conditions.

## Application Information

### Enable

The device can be enabled or disabled by the EN pin. When the EN pin is higher than the threshold of logic-high, the device starts operating with soft-start. Once the EN pin is set at low, the device will be shut down. In shutdown mode, the converter stops switching, internal control circuitry is turned off, and the load is disconnected from the input. This also means that the output voltage can drop below the input voltage during shutdown.

### Soft-Start State

After the successful completion of the LIN state ( $V_{OUT} \geq V_{IN} - 300\text{mV}$ ).

During Soft-Start state,  $V_{OUT}$  is ramped up by Boost internal loop. If  $V_{OUT}$  fails to reach target value during the Soft-Start period for more than 2ms, a fault condition is declared.

### Output Voltage Setting

User can select the output voltage level by VSEL and I2C. If the VSEL pulled low, the default is 3.3V, and if it pulled high, the default is 3.55V.

The output voltage range is from 2.85V to 4.4V.

### Power Save Mode

PSM is the way to improve efficiency at light load.

When the output voltage is lower than a set threshold voltage, the converter will operate in PSM.

It raises the output voltage with several pulses until the loop exits PSM.

### Under-Voltage Lockout

The under-voltage lockout circuit prevents the device from operating incorrectly at low input voltages. It prevents the converter from turning on the power switches under undefined conditions and prevents the battery from deep discharge.  $V_{IN}$  voltage must be greater than 1.7V to enable the converter. During operation, if  $V_{IN}$  voltage drops below 1.6V, the converter is disabled until the supply exceeds the UVLO rising threshold. The RT4803 automatically

restarts if the input voltage recovers to the input voltage UVLO high level.

### Thermal Shutdown

The device has a built-in temperature sensor which monitors the internal junction temperature. If the temperature exceeds the threshold, the device stops operating. As soon as the IC temperature has decreased below the threshold with a hysteresis, it starts operating again. The built-in hysteresis is designed to avoid unstable operation at IC temperatures near the over temperature threshold.

### Inductor Selection

The recommended nominal inductance value is 0.47 $\mu\text{H}$ .

It is recommended to use inductor with dc saturation current  $\geq 3500\text{mA}$

### Input Capacitor Selection

At least a 10 $\mu\text{F}$  input capacitor is recommended to improve transient behavior of the regulator and EMI behavior of the total power supply circuit for LX. And at least a 1 $\mu\text{F}$  ceramic capacitor placed as close as possible to the  $V_{IN}$  and GND pins of the IC is recommended.

### Output Capacitor Selection

At least 22 $\mu\text{F}$  x 2 capacitors is recommended to improve  $V_{OUT}$  ripple.

Output voltage ripple is inversely proportional to  $C_{OUT}$ .

Output capacitor is selected according to output ripple which is calculated as :

$$V_{\text{RIPPLE(P-P)}} = t_{\text{ON}} \times \frac{I_{\text{LOAD}}}{C_{\text{OUT}}}$$

and

$$t_{\text{ON}} = t_{\text{SW}} \times D = t_{\text{SW}} \times \left(1 - \frac{V_{\text{IN}}}{V_{\text{OUT}}}\right)$$

therefore :

$$C_{\text{OUT}} = t_{\text{SW}} \times \left(1 - \frac{V_{\text{IN}}}{V_{\text{OUT}}}\right) \times \frac{I_{\text{LOAD}}}{V_{\text{RIPPLE(P-P)}}$$

and

$$t_{\text{SW}} = \frac{1}{f_{\text{SW}}}$$

The maximum  $V_{RIPPLE}$  occurs when  $V_{IN}$  is at minimum and  $I_{LOAD}$  is at maximum.

### Output Discharge Function

With the EN pin set to low, the VOUT pin is internally connected to GND by an internal discharge N-MOSFET switch.

This feature prevents residual charge voltages on capacitor connected to VOUT pins, which may impact proper power up of the system.

### Current Limit

The RT4803 employs a valley-current limit detection scheme to sense inductor current during the off-time. When the loading current is increased such that the loading is above the valley current limit threshold, the off-time is increased until the current is decreased to valley-current threshold. Next on-time begins after current is decreased to valley-current threshold. On-time is decided by  $(V_{OUT} - V_{IN}) / V_{OUT}$  ratio. The output voltage decreases when further loading current increase. As the following figure shown, the current limit function is implemented by the scheme.

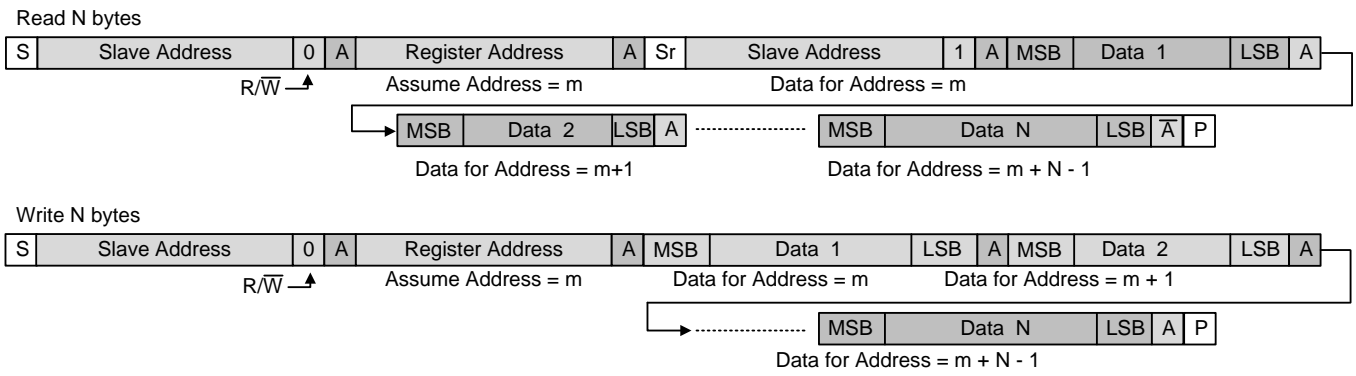

Figure 4. Inductor Currents In Current Limit Operation

**Register Table Lists [Slave address = 1110101 (0x75)]**

1	R	FAULT	0	0 : Normal operation. 1 : Indicates that a fault condition has occurred. This flag is reset after readout.
0	R	PGOOD	0	0 : Indicates the output voltage is out of regulation. 1 : Indicates the output voltage is within its nominal range. This bit is set if the converter is forced in pass-through mode.

**Thermal Considerations**

For continuous operation, do not exceed absolute maximum junction temperature. The maximum power dissipation depends on the thermal resistance of the IC package, PCB layout, rate of surrounding airflow, and difference between junction and ambient temperature. The maximum power dissipation can be calculated by the following formula :

$$P_{D(MAX)} = (T_{J(MAX)} - T_A) / \theta_{JA}$$

where  $T_{J(MAX)}$  is the maximum junction temperature,  $T_A$  is the ambient temperature, and  $\theta_{JA}$  is the junction to ambient thermal resistance.

For recommended operating condition specifications, the maximum junction temperature is 125°C. The junction to ambient thermal resistance,  $\theta_{JA}$ , is layout dependent. For WL-CSP-16B 1.67x1.67 (BSC) package, the thermal resistance,  $\theta_{JA}$ , is 47.7°C/W on a standard JEDEC 51-7 four-layer thermal test board. The maximum power dissipation at  $T_A = 25^\circ\text{C}$  can be calculated by the following formula :

$$P_{D(MAX)} = (125^\circ\text{C} - 25^\circ\text{C}) / (47.7^\circ\text{C/W}) = 2.09\text{W for WL-CSP-16B 1.67x1.67 (BSC) package}$$

The maximum power dissipation depends on the operating ambient temperature for fixed  $T_{J(MAX)}$  and thermal resistance,  $\theta_{JA}$ . The derating curve in Figure 5 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

Figure 5. Derating Curve of Maximum Power Dissipation

**Layout Consideration**

The PCB layout is an important step to maintain the high performance of the RT4803.

Both the high current and the fast switching nodes demand full attention to the PCB layout to save the robustness of the RT4803 through the PCB layout. Improper layout might show the symptoms of poor line or load regulation, ground and output voltage shifts, stability issues, unsatisfying EMI behavior or worsened efficiency. For the best performance of the RT4803, the following PCB layout guidelines must be strictly followed.

- ▶ Place the input and output capacitors as close as possible to the input and output pins respectively for good filtering.
- ▶ For thermal consider, it needed to maximize the pure area for the power stage area besides the LX.

Figure 6. PCB Layout Guide

Outline Dimension

Symbol	Dimensions In Millimeters		Dimensions In Inches	
	Min	Max	Min	Max
A	0.500	0.600	0.020	0.024
A1	0.170	0.230	0.007	0.009
b	0.240	0.300	0.009	0.012
D	1.620	1.720	0.064	0.068
D1	1.200		0.047	
E	1.620	1.720	0.064	0.068
E1	1.200		0.047	
e	0.400		0.016
